## Abstract

The last decades have seen the rise of many fundamental chronological debates in Old World archaeology, with far-reaching historical implications. Yet, outside of radiocarbon dating—where Bayesian formal tools and models are applied—these chronological debates are still relying on non-formal models, and dates are mostly derived by hand, without the use of mathematical or computational tools, albeit the large number of complex constraints to be taken into account. This article presents formal models and algorithms for encoding archaeologically-relevant chronological constraints, computing optimal chronologies in an automated way, and automatically checking for chronological properties of a given model. These techniques are partly inspired from those (namely zones and DBMs) that have been developed in the setting of automated analysis of timed automata.

## 1 Introduction

### 1.1 Motivation

Reconstructing ancient chronologies based on archaeological data is a complex task, which has haunted researchers since the start of the discipline. Current chronologies of given regions result from an integration of diverse data such as historical records (providing regnal dynasties for example), pottery sequences (providing relative chronologies for a given region), stratigraphic sequences (providing synchronisms through stratified pottery and artefacts, both local and imported), ancient inscriptions (providing synchronisms between different kings for example) and laboratory methods (providing date-ranges for a given event, through radiocarbon dating for example). In most cases, these data constitute a complex web of intricate information, connecting archaeological data of neighbouring sites and regions in a subtle way. Hence, any change in chronological hypotheses at one end of the network (say, changing the historical dates of a given king for example) can have far-reaching chronological repercussions throughout the network (say for example that inscriptions of this king have been found in a specific archaeological layer, bearing specific pottery types). How can we model such constraints formally, and how can we use our formal model to automatically derive a global chronology for a region of interest, through the integration of several scattered local chronological constraints? We have observed that, outside of carbon dating, where Bayesian statistical tools are used to formally derive date estimates [14], traditional chronological research still uses no formal model or algorithm to integrate sets of local chronological constraints into a global chronology. In most cases (outside of radiocarbon dating), the date estimates proposed by researchers are derived by hand, thus certainly obtaining non-optimal results, since manual treatment of any set of chronological constraints of non-trivial size is almost impossible. The purpose of this paper is to present a model that allows to formally model archaeologically-relevant chronological constraints, to compute optimal chronologies through specific algorithms, and to automatically check

chronological properties of a given model. Applications of such models are numerous, since the past decades have seen the rise of many important—and still unsettled—chronological debates in Old World archaeology, with far-reaching historical implications. Important recent examples of such debates include the Thera Eruption debate, where two opposing chronologies differ by *more than a century*, with important implications regarding the chronology of the Aegean Bronze Age [8]. A second well-known example is the Iron Age Low Chronology debate for the southern Levant, where two chronologies differ as to whether the first full-fledged territorial states in the region are to be dated to the 10<sup>th</sup> or the 9<sup>th</sup> century BCE [13].

## 1.2 Running example

As a didactic example of the kind of data and constraints that typically appear in chronological debates, we will start with a small test case, in order to show that even small examples, with far less constraints than any real archaeological case study, are impractical to manual treatment and require a formal and algorithmic approach. The test case is called Chronoland, and is presented hereinafter.

**The story of Chronoland.** In the kingdom of Chronoland, Kings  $K_1$  and  $K_2$  reigned in succession. We do not know their precise reign dates, but both reigns are known to have occurred between 1200 and 1300 CE. Furthermore,  $K_1$ ’s reign did not exceed 15 years, since we know he died at a rather young age, and King  $K_2$  reigned for at least 30 complete years, since we have a monument dated to his 31<sup>st</sup> year<sup>1</sup>. We can also safely assume that  $K_2$ ’s reign did not exceed 100 years. Now ChronoCity,

<sup>1</sup> We use a cautious bound of 30 years instead of 31 years because we do not know if the king completed his 31<sup>st</sup> year of reign (i.e. he might have died in the course of his 31<sup>st</sup> year).

the capital city of Chronoland, was excavated and only two strata were found, namely strata  $S_1$  and  $S_2$ . We know that stratum  $S_1$  was built by King  $K_1$  since he thus claims in a stela found there in-situ, and we also know that Stratum  $S_2$  ended during the reign of King  $K_2$ , since ancient annals tell us that the city was destroyed during his reign and never reoccupied. Finally, we assume that each one of our strata has a duration of at least 20 years and at most 100 years. The data of the example are given in schematic form in Figure 1, and several natural questions can be asked about it, such as:

1. What are the most precise estimates (ranges) we can gather for the start date, end date and duration of each king and stratum of Chronoland?
2. Has King  $K_1$  built stratum  $S_2$ ? (Recall that the data only asserts he has built  $S_1$ .)

Observe that the second question could admit three different answers because of the uncertainties on the dates: (i) ‘yes’,  $K_1$  has surely built  $S_2$ , in all possible scenarios that fit with the constraints on the dates and durations; or (ii) ‘no’,  $K_1$  has surely not built  $S_2$  (again in all possible scenarios); or (iii) ‘maybe’, i.e. some dates that respect the constraints, imply that  $K_1$  has built  $S_2$ , and some don’t.

**Chronology computation.** We start by discussing the first question (optimal ranges). These optimal estimates are shown in Figure 2. One can easily see that they are not straightforward and require a close look at the model. Here are the steps that one could follow to obtain these results:

1. **Initialisation.** The date ranges of  $K_1$  and  $K_2$  can be improved using the duration estimates. The 30 years minimum duration of  $K_2$  imply that  $K_2$  starts in [1200,1270] and that it ends in [1230,1300].
2.  **$K_1$ – $K_2$  sequence.** The end of  $K_1$  equals the start of  $K_2$ , hence it is in [1200,1270]. The start of  $K_1$  is thus also in [1200,1270], since a start date cannot exceed its corresponding end date.
3.  **$S_1$ – $K_1$  synchronism.** The ‘ $S_1$  starts during  $K_1$ ’ synchronism implies that the start of  $S_1$  is in [1200,1270]. The [20,100] duration range now implies that the end of  $S_1$  is in [1220,1370].
4.  **$S_1$ – $S_2$  sequence.** The start of  $S_2$  equals the end of  $S_1$ , hence it is in [1220,1370]. The [20,100] duration range now implies that the end of  $S_2$  is in [1240,1470].
5.  **$S_2$ – $K_2$  synchronism.** The ‘ $S_2$  ends during  $K_2$ ’ synchronism implies that the end of  $S_2$  is in [1240,1300]. The [20,100] duration range now implies that the start of  $S_2$  is in [1220,1280]. The duration range can now be reduced to [20,80] since the earliest start of  $S_2$  is 1220 and its latest end is 1300.
6.  **$S_1$ – $S_2$  sequence.** The end of  $S_1$  equals the start of  $S_2$ , hence it is in [1220,1280]. The [20,100] duration range now implies that the start of  $S_1$  is in [1200,1260]. The duration range can now be reduced to [20,80] since the earliest start of  $S_1$  is 1200 and its latest end is 1280.
7.  **$S_1$ – $K_1$  synchronism.** We need to come back to the ‘ $S_1$  starts during  $K_1$ ’ synchronism. Our new upper bound of 1260 on  $S_1$ ’s start needs to be propagated back to  $K_1$ , implying a new improved range of [1200,1260] on  $K_1$ ’s start, instead of the former [1200,1270].
8.  **$S_2$ – $K_2$  synchronism.** Finally, we need to consider anew the ‘ $S_2$  ends during  $K_2$ ’ synchronism. Our new lower bound of 1240 on  $S_2$ ’s end needs to be propagated back to  $K_2$ , implying a new improved range of [1240,1300] on  $K_2$ ’s end, instead of the former [1230,1300].

Note the difficulty of manually solving this simple problem, especially the final ‘retro-action’ step, where  $K_1$ ’s start date and  $K_2$ ’s end date get further refined by 10 years thanks to their synchronisms with  $S_1$  and  $S_2$  respectively. This final step is somewhat unexpected since  $S_1$  and  $S_2$  had no a priori absolute chronology of their own (they had only duration estimates), and thus derived their absolute dates from  $K_1$  and  $K_2$ . Now, let us come back to the question whether king  $K_1$  has built stratum  $S_2$ . It turns out that this is impossible, because  $K_1$ ’s reign lasts at most 15 years, but at least 20 years separate the respective start dates of  $S_1$  and  $S_2$ , since  $S_1$  lasts at least 20 years. However, again, deriving this information from Figure 1 or Figure 2 is not straightforward. Also note that this example is of small

dimensions compared to real archaeological data for which manual treatment of the information is practically impossible.

### 1.3 Contribution

As can be seen from the Chronoland example, rigorous and automatic techniques for reasoning about chronological problems are needed. To the best of our knowledge, no such techniques are available today, and the kind of reasoning we exhibit in the Chronoland example are performed ‘by hand’ by archaeologist, using restricted data sets. In this paper, **our first contribution is a formal constraint language (Section 2) that can express most relationships between periods which are needed for practical cases of archaeology.** More precisely, our language can express: (i) lower and upper bounds on the start dates, end dates and durations of periods; (ii) sequences (such as period  $S_2$  follows directly  $S_1$ ); and (iii) different kinds of synchronisms between periods (such as ‘ $S_1$  starts during  $K_1$ ’, etc). Then, **our second contribution consists of several algorithmic techniques (Section 3) to manipulate such constraints and extract information that is meaningful to archaeologists,** namely: (i) what are the *tightest bounds* on the start dates, end dates and durations of all periods that one can infer from a given set of constraints? (ii) is the set of constraints *satisfiable*. That is, is it possible to assign dates to the starts and ends of all periods that satisfy all the constraints? (iii) do the constraints *imply* that two given periods have a non-empty intersection? That is, is the intersection guaranteed to exist, for all choices of start and end dates of the periods that satisfy the constraints? We call this problem the *sure-contemporaneity* problem; and, finally (iv) do the constraints *allow* a non-empty intersection between two periods? That is, does there *exist* a choice of dates for the starts and ends of all periods that satisfy the constraints and where the two given periods intersect? We call this problem the *possible-contemporaneity* problem. Observe that both the sure- and possible-contemporaneity problems can be invoked to answer our question: ‘Has  $K_1$  built  $S_2$ ?’

Following [16], we translate our constraints in directed weighted graphs, and reduce the computation of the tightest bounds to an all-pair shortest paths computation in this graph (and, as particular case, we obtain an algorithm for the satisfiability problem which amounts to detecting negative cycles in the graph). Such computation can be carried out *in polynomial time* (in the number of periods) using classical algorithms [12], which is a clear strong point of approach, enabling scaling to examples of big dimensions. Since all-pairs shortest paths algorithms also detect negative cycle, we can also test satisfiability in polynomial time<sup>2</sup>. Finally, we show that, after computation of the shortest paths, the sure- and possible-contemporaneity problems can be solved *in constant time*.

### 1.4 Related works

The best known use of computer-assisted techniques in Archaeology is in a setting which is different from ours, namely the calibration of radiocarbon dates [14] thanks to the OxCal software. The aim of Oxcal is to refine estimates of dates computed from radiocarbon samples, by taking into account extra information such as the order of strata. Due to the stochastic nature of radiocarbon decay, these methods are probabilistic (they rely on Bayes’s theorem) while our methods are not.

Concerning relative chronology, other formal approaches exist, based on the Harris matrix [7] or the generalised schemes of Sharon [15] and Holst [9]. These works differ from ours in several way. First, they aim at obtaining a feasible sorting of the archaeological features, but do not estimate their absolute time-frame, while our method provides both *absolute* and *relative* information on the periods. Second, the underlying computational problem they address is NP-complete (hence, they rely on

---

<sup>2</sup> Similar techniques are used in the setting of timed automata, see related works.

heuristics), while we have identified problems that can be solved in polynomial time. In fact, an early paper by Kromholz [11] already combined some relative and absolute dating elements, though in a limited way, through the application of business-oriented tools (such as Pert charts) to chronological problems. We are not aware however of any later paper that took on this novel approach.

On the other hand, the constraints we rely on are actually a special case of the *zone* data structure developed in the framework of *timed automata* [1, 6, 3]. The zone data structure, together with their implementations as Difference Bound Matrices, have been extensively studied and form the cornerstone of efficient tools [4] for the analysis of timed automata such as UPPAAL [2] and TIAMO [5]. In our setting, however, constraints are simpler since the values of the variables (representing endpoints of periods) take discrete (natural) values, whereas with timed automata the variables (i.e., *clocks* in the timed automata setting) are real-valued.

## 2 Modelling chronology problems

In this section, we introduce our model for the chronology problems we have sketched in the introduction. Throughout the paper, we denote the set of natural and integers numbers by  $\mathbb{N}$  and  $\mathbb{Z}$  respectively. We consider closed interval on  $\mathbb{N}$  (i.e., convex subsets of  $\mathbb{N}$ ), with natural endpoints. We use the usual notation  $[a, b]$  to denote intervals, and for  $I = [a, b]$ , we let  $\ell(I) = a$  and  $u(I) = b$ .

### 2.1 Periods and chronologies

**Periods.** We fix a finite set  $\mathcal{P}$  of *periods*. We use the general term ‘period’ to speak about continuous periods of time characterised by a start date, an end date and a duration (defined as the difference between the end and start dates)<sup>3</sup>. Examples of periods include historical eras (‘The Middle Ages’), archaeological strata, king’s reigns and ceramic periods, among others.

**Chronologies.** A *chronology*  $\mathcal{C}$  on a set of periods  $\mathcal{P}$  is function that associates, to each period  $p \in \mathcal{P}$ , an interval  $\mathcal{C}(p) = [a_p, b_p] \subset \mathbb{N}$  with natural endpoints  $a_p$  and  $b_p$ . For all periods  $p$ , the interval  $\mathcal{C}(p)$  represents the whole duration of the period, in the sense that its endpoints represent the start and the end *dates* of the period. Throughout the paper, we assume that all dates are given simply as years, but a finer granularity can be used if need be (for example, dates can represent days). Observe that, for historical events, start and end dates could be negative, but we assume that there is a lower bound on all dates<sup>4</sup> (i.e., an ‘origin of time’), which we identify with 0 (hence we have  $a_e, b_e \geq 0$  for all  $e \in \mathcal{P}$ ). A chronology  $\mathcal{C}$  for our running example could be s.t.  $\mathcal{C}(K_1) = [1210, 1222]$ , which is compatible with the constraints in Figure 1.

### 2.2 Constraints

**Common chronological constraints.** Our goal is to formalise a large set of chronological constraints relevant to archaeology and history. In these fields, the most common constraints can be grouped in three families:

**Bounds** The first family consists of lower and upper bounds on the start date, end date and duration of a period. For example, in Figure 1, the  $[20, 100]$  years constraint on  $S_1$ ’s duration, or the  $[1200, 1300]$  constraint on  $K_1$ ’s start date belong to this family.

<sup>3</sup> Punctual events could be seen as special cases of periods have equal start and end dates, and null duration.

<sup>4</sup> In practice, this is not restrictive since events can always be associated to an epoch, even if this is very broad.

**Sequences** The second family expresses that a certain period starts where the preceding period ends, as in the  $K_1, K_2$  sequence, and the  $S_1, S_2$  sequence.

**Synchronisms** Finally, the third family expresses diverse sorts of *synchronisms*, such as contemporaneity (two periods having a non-empty intersection, as in two contemporary kings), ‘starts during’ (as in ‘ $S_1$  starts during  $K_1$ ’) and ‘ends during’ (as in ‘ $S_2$  ends during  $K_2$ ’).

Let us now discuss a formal constraint language that allows us to describe all these constraints.

**A formal model of constraints.** To all finite sets of periods  $\mathcal{P} = \{p_1, \dots, p_n\}$ , we associate a set of *variables*  $\mathcal{V}(\mathcal{P}) = \{z_0, \text{beg}(p_1), \text{end}(p_1), \dots, \text{beg}(p_n), \text{end}(p_n)\}$ , interpreted over the integers. For each period  $p_i$ , variables  $\text{beg}(p_i)$  and  $\text{end}(p_i)$  represent respectively the beginning and end of  $p_i$ . Variable  $z_0$  is a special variable that is assumed to be always equal to 0 and its purpose will become clear later. Then, an atomic constraint on  $\mathcal{P}$  is an expression of one of the following forms: either  $x - y \sim c$  or  $x \sim c$ , where  $x, y$  are variables from  $\mathcal{V}(\mathcal{P})$ ,  $c \in \mathbb{Z} \cup \{+\infty\}$ , and  $\sim$  is either  $\leq$  or  $\geq$  or  $=$ . Finally, a *constraint* is a finite *conjunction* of atomic constraints<sup>5</sup>. For an atomic constraint  $\psi$  and a constraint  $\phi$ , we write  $\psi \in \phi$  iff  $\psi$  is a conjunct of  $\phi$ .

**Semantics.** Let us now define the semantics of constraints in terms of chronologies. Intuitively, a constraint is meant to define a set of *possible chronologies*, which are all those that are compatible with the constraint. Formally, a chronology  $\mathcal{C}$  (on set of periods  $\mathcal{P}$ ) *satisfies* an atomic constraint  $x - y \sim c$  (respectively,  $x \sim c$ ) iff  $v(x) - v(y) \sim c$  (respectively,  $v(x) \sim c$ ), where  $v : \mathcal{V}(\mathcal{P}) \rightarrow \mathbb{N}$  is the function associating to each variable  $x$  a *valuation* according to  $\mathcal{C}$ , i.e., for all  $x \in \mathcal{V}(\mathcal{P})$ :

$$v(x) = \begin{cases} 0 & \text{if } x = z_0 \\ \ell(\mathcal{C}(e)) & \text{if } x = \text{beg}(e) \\ u(\mathcal{C}(e)) & \text{if } x = \text{end}(e). \end{cases}$$

When a chronology  $\mathcal{C}$  satisfies an atomic constraint  $\psi$ , we write  $\mathcal{C} \models \psi$ . We extend this notion of satisfaction to constraints:  $\mathcal{C}$  satisfies a constraint  $\phi = \psi_1 \wedge \psi_2 \wedge \dots \wedge \psi_n$  (noted  $\mathcal{C} \models \phi$ ) iff  $\mathcal{C}$  satisfies all conjuncts of  $\phi$ , i.e.,  $\mathcal{C} \models \psi_i$  for all  $1 \leq i \leq n$ . We denote by  $\llbracket \phi \rrbracket$  the set of all chronologies  $\mathcal{C}$  s.t.  $\mathcal{C} \models \phi$ . Remark that this set could be empty, for instance if we have specified constraints that are not satisfiable. Note also that two different constraints can encode the same chronologies, e.g. when there are redundant atomic constraints. For example,  $\phi = x \geq 0 \wedge x \leq 1 \wedge y \geq 0 \wedge y \leq 1$  encodes the same chronologies as  $\phi' = \phi \wedge x - y \leq 5$ , (i.e.,  $\llbracket \phi \rrbracket = \llbracket \phi' \rrbracket$ ) because  $\phi$  *implies*  $x - y \leq 5$ .

**Expressiveness of the model.** While the language of constraints we have just defined might seem very restrictive, we claim that it allows to define most of the relevant constraints in archaeology, as defined at the beginning of this section:

**Terminus post quem.** A *Terminus post quem* is defined as a lower bound  $B$  on a given start or end date. Such constraints can be expressed by  $\text{beg}(p) \geq B$  and  $\text{end}(p) \geq B$ , respectively.

**Terminus ante quem.** Symmetrically, a *Terminus ante quem* is defined as an upper bound  $B$  on a given start or end date. Such constraints correspond to  $\text{beg}(p) \leq B$  and  $\text{end}(p) \leq B$ , respectively.

**Date range.** Ranges on dates are the conjunction of a *terminus post* and *ante quem*. In the example of Figure 1, the constraint on the start of  $K_1$  is expressed as:  $\text{beg}(K_1) \geq 1200 \wedge \text{beg}(K_1) \leq 1300$ .

**Duration constraints.** Since the duration of a period  $p$  can be computed as  $\text{end}(p) - \text{beg}(p)$ , constraints (lower bounds, upper bound or ranges) on the duration of a period also fit our model.

<sup>5</sup> Observe that neither disjunction nor negation are allowed.

In the example of Figure 1, the range on the duration of  $K_1$  is expressed as:  $\text{end}(K_1) - \text{beg}(K_1) \geq 0 \wedge \text{end}(K_1) - \text{beg}(K_1) \leq 15$ .

**Sequence.** A sequence of periods  $p$  and  $q$  means that  $q$  follows immediately after  $p$ . Thus, the end date of  $p$  is the start date of  $q$ , which is formalised as:  $\text{end}(p) - \text{beg}(q) = 0$ .

**‘Contemporaneity’ synchronism.** Periods  $p$  and  $q$  are contemporary, i.e. there is a non-empty intersection between the intervals  $I_p = [\text{beg}(p), \text{end}(p)]$  and  $I_q = [\text{beg}(q), \text{end}(q)]$ . To understand how to model this, we consider the opposite statement: the intersection between  $I_p$  and  $I_q$  is empty iff either  $I_p$  follows strictly  $I_q$  or  $I_q$  follows strictly  $I_p$ . That is,  $I_p \cap I_q = \emptyset$  iff  $\text{end}(p) < \text{beg}(q) \vee \text{end}(q) < \text{beg}(p)$ . This can be expressed by our constraints by taking the negation:  $I_p \cap I_q \neq \emptyset$  iff  $\text{end}(p) \geq \text{beg}(q) \wedge \text{end}(q) \geq \text{beg}(p)$ .

**‘Starts during’ synchronism.** Period  $p$  starts during period  $q$ , i.e. the start of  $p$  is included in the interval  $[\text{beg}(q), \text{end}(q)]$ . This is formalised as:  $\text{beg}(p) \geq \text{beg}(q) \wedge \text{beg}(p) \leq \text{end}(q)$ .

**‘Ends during’ synchronism.** Period  $p$  ends during period  $q$ , i.e. the end of  $p$  is included in the interval  $[\text{beg}(q), \text{end}(q)]$ . This is formalised as:  $\text{end}(p) \geq \text{beg}(q) \wedge \text{end}(p) \leq \text{end}(q)$ .

**‘Inclusion’.** Period  $p$  is included in period  $q$ , which can be formalised in our model as:  $\text{beg}(p) - \text{beg}(q) \geq 0 \wedge \text{end}(p) - \text{end}(q) \leq 0$ .

In addition to these constraints that come from the archaeological data, we *assume* from now on that all our constraints *imply* that all periods must start before they end. This can be achieved by taking the conjunction of any constraint with:

$$\bigwedge_{p \in \mathcal{P}} \text{beg}(p) \leq \text{end}(p).$$

Observe that one type of requirement that our constraints cannot express is *non-contemporaneity*, i.e. that the intersection between two periods  $p$  and  $q$  is empty. Indeed, non-contemporaneity means that *either* the end of  $p$  occurs strictly before the beginning of  $q$  *or* end of  $q$  occurs strictly before the beginning of  $p$ . However, our constraint language does not allow on to express disjunction.

### 2.3 Normalisation of constraints

In order to make our subsequent discussions easier, we will, from now on, consider a *normal form* for constraints, where constraints contain atomic constraints of the form  $x - y \leq c$  only. Let  $\varphi$  be a constraint. We obtain  $\text{Norm}(\varphi)$ , the normal form of  $\varphi$  by applying the following steps:

1. First, we make sure that there exists at least one atomic constraint for each pair of variables  $x$  and  $y$ , by taking the conjunction of  $\varphi$  with:

$$\bigwedge_{x \in \mathcal{V}(\mathcal{P})} (x - x \leq 0 \wedge x - z_0 \leq +\infty \wedge z_0 - x \leq 0) \wedge \bigwedge_{x, y \in \mathcal{V}(\mathcal{P}) \setminus \{z_0\}} x - y \leq +\infty$$

It is easy to check that the resulting constraint accepts the same set of chronologies than  $\varphi$ . Indeed, since we assume that  $z_0$  is always null:  $x - x \leq 0$  is equivalent to  $x \leq x$ ;  $x - z_0 \leq +\infty \wedge z_0 - x \leq 0$  is equivalent to  $0 \leq x \leq +\infty$ ; and  $x - y \leq +\infty$  should hold for all  $x, y$  since they take finite values.

2. We turn all atomic constraints into constraints of the form  $x - y \leq c$ . That is, we replace all atomic constraints  $x \sim c$  by  $x - z_0 \sim c$ ; and all constraints  $x - y \geq c$  by  $y - x \leq -c$ .
3. Finally, whenever there are two different atomic constraints of the form  $x - y \leq c$  and  $x - y \leq c'$  in the resulting constraint, we keep the strongest one, i.e.  $x - y \leq c$  if  $c < c'$  and  $x - y \leq c'$  otherwise.

The resulting is a normalised constraint  $\text{Norm}(\varphi)$  which contains exactly  $(2n + 1)^2$  atomic constraints of the form  $x - y \leq c$ , where  $n$  is the number of periods; one for each pair of variables  $x$  and  $y$  in  $\mathcal{V}(\mathcal{P})$ . *From now on, we assume that all constraints are normalised.* We abuse notations and

denote normalised constraint by non-normalised ones, writing, for instance,  $x - y \leq 1$  instead of  $\text{Norm}(x - y \leq 1)$  which has 9 conjuncts.

Observe that this particular class of linear constraints has been studied before by Shostak [16]. They also form a special case of zones [1], and the normalised version of the constraint correspond to the Difference Bound Matrix [6] encoding the corresponding zone.

► **Example 1.** Consider again the example in Figure 1. In order to keep our example legible, we will consider only stratum  $S_1$ , king  $K_1$  and the ‘starts during’ relationship between them. The following normalised constraint expresses exactly all the information from Figure 1 about  $S_1$  and  $K_1$ , assuming  $\mathcal{X} = \{z_0, \text{beg}(S_1), \text{beg}(K_1), \text{end}(S_1), \text{end}(K_1)\}$ . Observe that the five last lines (marked ‘Norm.’) are here for normalisation purpose only.

### 3 Algorithmic manipulation of constraints

In this section, we show how the constraints from Section 2 can be manipulated algorithmically to answer the questions we have highlighted in introduction. We start by defining four meaningful problems on constraints, then show how the constraints can be expressed by means of weighted directed graphs, and finally give polynomial-time algorithms to solve those problems on the graphs. The main ideas of these techniques have been presented by Shostak [16], but our techniques for solving the sure- and possible- contemporaneity problems (that are motivated by the archaeological setting) are, as far as we know, original (and hence require dedicated proofs).

#### 3.1 Four basic problems

Based on the motivations from the introduction, we focus on the four following problems.

**Satisfiability.** First, the *satisfiability* problem asks whether there is some chronology that satisfies a given constraint. If not, then the constraint contains a contradiction, for example: the constraint entails that some punctual period  $A$  should occur strictly before  $B$ , and, at the same time, that  $B$  should occur before  $A$ . Thus, the definition of this problem is as follows:

► **Problem 2.** *Given a constraint  $\varphi$ , the satisfiability problem asks whether  $\llbracket \varphi \rrbracket \neq \emptyset$ ?*

If yes, we say that the constraint  $\varphi$  is *satisfiable*.

**Tightening.** Second, the *tightening* problem asks, given a constraint  $\varphi$ , to compute the tightest constraint  $\varphi'$  that represents the same set of chronologies. Intuitively,  $\varphi'$  represents the most precise information one can deduce from  $\varphi$ . Let us first define formally these notions.

Given two atomic constraints  $\psi_1 = x - y \leq c_1$  and  $\psi_2 = x - y \leq c_2$  (on the same variables  $x$  and  $y$ ), we say that  $\psi_1$  is *tighter* than  $\psi_2$  (denoted  $\psi_1 \preceq \psi_2$ ) iff  $c_1 \leq c_2$ . Intuitively, a constraint is *tighter* than another if it imposes a more stringent limitation on the possible values of the variables than the other (hence, the upper bound  $c_1$  is smaller than or equal to  $c_2$ ). Then, given two (normalised) constraints  $\varphi_1$  and  $\varphi_2$  on  $\mathcal{P}$ , we say that  $\varphi_1$  is *tighter* than  $\varphi_2$  (denoted  $\varphi_1 \preceq \varphi_2$ ) iff each atomic constraint of  $\varphi_1$  is tighter than the corresponding constraint in  $\varphi_2$ . Formally,  $\varphi_1 \preceq \varphi_2$  iff for all  $x, y$  in  $\mathcal{V}(\mathcal{P})$ :  $\psi_1 = x - y \leq c_1 \in \varphi_1$  and  $\psi_2 = x - y \leq c_2 \in \varphi_2$  implies that  $\psi_1 \preceq \psi_2$ .

Observe that  $\preceq$  is a partial order on constraints, which is not total. For instance,  $x_1 - y_1 \leq 1 \wedge x_2 - y_2 \leq 2$  and  $x_1 - y_1 \leq 2 \wedge x_2 - y_2 \leq 1$  are not comparable. Our definition of the order on constraints *implies* the intuition on the sets of chronologies they represent, i.e., for all constraints  $\varphi_1$  and  $\varphi_2$ :  $\varphi_1 \preceq \varphi_2$  implies  $\llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket$ . However, the converse is not true. For instance, consider:  $\varphi_1 = \text{Norm}(x - y \leq 1 \wedge y - z \leq 1)$ , and  $\varphi_2 = \text{Norm}(x - y \leq 1 \wedge y - z \leq 1 \wedge x - z \leq 2)$ . It is easy to check that  $\llbracket \varphi_1 \rrbracket = \llbracket \varphi_2 \rrbracket$  since the  $x - z \leq 2$  atomic constraint of  $\varphi_2$  is implied by its two other atomic constraints. Hence, in particular  $\llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket$ , but, clearly  $\varphi_1 \not\preceq \varphi_2$ , because  $\varphi_1$  constraints  $x - z$  to be  $\leq +\infty$ , which is strictly weaker than  $x - z \leq 2$ . We can now define precisely the *tightening problem*:

► **Problem 3.** Given a constraint  $\varphi$ , the tightening problem asks to compute the tightest (i.e., minimal wrt  $\preceq$ ) constraint  $\varphi'$  s.t.  $\llbracket \varphi' \rrbracket = \llbracket \varphi \rrbracket$ . Such a constraint  $\varphi'$  is called *tight*.

Remark that this constraint  $\varphi'$  is necessarily unique. Indeed, assume it is not the case, and there are two constraints  $\varphi'_1$  and  $\varphi'_2$  s.t.  $\llbracket \varphi'_1 \rrbracket = \llbracket \varphi'_2 \rrbracket = \llbracket \varphi \rrbracket$ ;  $\varphi'_1 \preceq \varphi$ ;  $\varphi'_2 \preceq \varphi$ , but  $\varphi'_1$  and  $\varphi'_2$  are not comparable by  $\preceq$  (that is, neither is tighter than the other). Then, we can consider instead the constraint  $\xi$  computed as follows: for each pair of variables  $x$  and  $y$ , we have in  $\xi$  the atomic constraint  $x - y \leq \min(c_1, c_2)$ , where  $c_1$  and  $c_2$  are the constants occurring in the atomic constraints on  $x - y$  in  $\varphi'_1$  and  $\varphi'_2$  respectively (i.e.,  $x - y \leq c_1 \in \varphi'_1$  and  $x - y \leq c_2 \in \varphi'_2$ ). By definition  $\xi \preceq \varphi'_1$  and  $\xi \preceq \varphi'_2$ . Hence,  $\xi \preceq \varphi$ . Moreover, since  $\llbracket \varphi'_1 \rrbracket = \llbracket \varphi'_2 \rrbracket$ , we also have  $\llbracket \xi \rrbracket = \llbracket \varphi'_1 \rrbracket = \llbracket \varphi'_2 \rrbracket$ , hence  $\llbracket \xi \rrbracket = \llbracket \varphi \rrbracket$ . Thus,  $\xi$  is an even tighter constraint that can be used instead of  $\varphi'_1$  and  $\varphi'_2$ .

**Sure-contemporaneity.** Third, the *sure-contemporaneity problem* asks whether two given periods  $p_1$  and  $p_2$  do *certainly* have a non-empty intersection given a constraint  $\varphi$ :

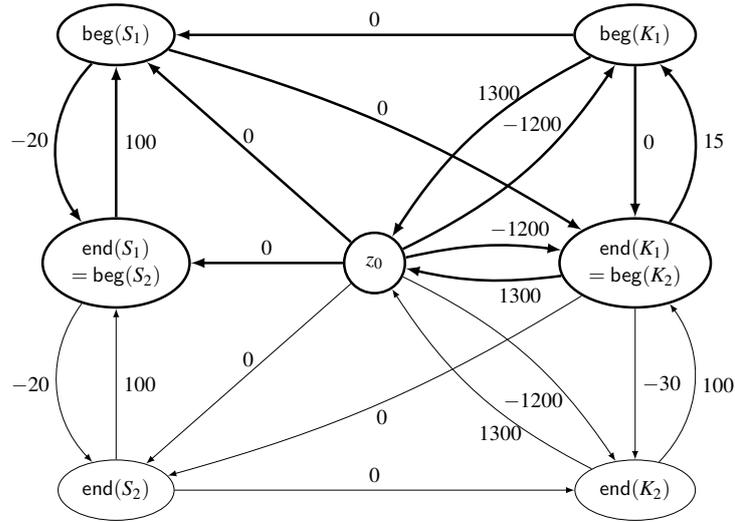

► **Problem 4.** The Sure-Contemporaneity Problem asks, given a constraint  $\varphi$  (on set of periods  $\mathcal{P}$ ) and two periods  $p_1$  and  $p_2$  in  $\mathcal{P}$ , whether  $\varphi$  guarantees that  $p_1$  and  $p_2$  intersect, i.e., whether  $\mathcal{C}(p_1) \cap \mathcal{C}(p_2) \neq \emptyset$  for all  $\mathcal{C} \in \llbracket \varphi \rrbracket$

**Possible-contemporaneity.** Fourth, the *Possible-Contemporaneity problem* asks whether two given periods  $p_1$  and  $p_2$  can *possibly* have a non-empty intersection given a constraint  $\varphi$ :

► **Problem 5.** The possible-contemporaneity problem asks whether a given constraint  $\varphi$  does not exclude a contemporaneity between two given periods  $p_1$  and  $p_2$ , i.e. whether there is  $\mathcal{C} \in \llbracket \varphi \rrbracket$  s.t.  $\mathcal{C}(p_1) \cap \mathcal{C}(p_2) \neq \emptyset$ .

## 3.2 Graph-based algorithms

Let us now present polynomial time algorithms for solving the four problems highlighted in the previous section. The core of our approach consists, following Shostak [16], in translating each constraint  $\varphi$  into a directed weighted graph  $G_\varphi$ . Roughly speaking, the set of nodes in  $G_\varphi$  is the set of variables of  $\varphi$ , and each constraint  $x - y \leq c$  is translated by a directed edge from  $x$  to  $y$ , labelled by  $c$ .

■ **Figure 3** The graph Chrono for the constraint in Figure 1. To simplify presentation, nodes  $end(K_1)$  and  $beg(K_2)$  (respectively  $end(S_1)$  and  $beg(S_2)$ ) have been merged and 0-labelled self-loops on the all nodes are not displayed. The bold part of the graph corresponds to the constraints on  $S_1$  and  $K_1$  only (see Example 1).

More precisely, in our setting, a graph  $G = \langle V, E, w \rangle$  is made up of a finite set of vertices  $V$ , a finite set of (directed) edges  $E \subseteq V \times V$  and a weight function  $w : E \rightarrow \mathbb{Z}$ . Given a constraint  $\varphi$  on a set of periods  $\mathcal{P}$ , we build the graph  $G_\varphi = \langle V, E, w \rangle$  as follows:

- $V = \mathcal{V}(\mathcal{P})$ , i.e. there is a vertex for each variable in the constraint;
- $E = \{(x, y) \mid x - y \leq c \in \varphi \text{ and } c \neq +\infty\}$ ; and
- for all  $(x, y) \in E$ :  $w(x, y) = c$  iff  $x - y \leq c \in \varphi$ . That is, there is an edge from  $x$  to  $y$ , labelled by  $c$  every time  $\varphi$  contains a non-trivial atomic constraint  $x - y \leq c$  (by ‘non-trivial’, we mean that  $c$  is not  $+\infty$ ). Thus, the edges encode exactly the set of  $\varphi$ ’s atomic constraints.

► **Example 6.** The graph corresponding to the full constraint modelling Chronoland (Figure 1) is given in Figure 3. The bold part of the graph corresponds to the constraint given in Example 1 (ranging on  $S_1$  and  $K_1$  only).

Now, we introduce our algorithms for our four problems given above.

**Satisfiability checking and tightening.** We address these two problems together as satisfiability can clearly be checked from the tightening of the constraint: clearly,  $\varphi$  is satisfiable iff the tightening of  $\varphi$  yields a constraint  $\xi$  s.t.  $\llbracket \xi \rrbracket \neq \emptyset$ . As said before, we rely on previous works for satisfiability and tightening. We start by recalling classical notions on graphs. Given a directed weighted graph  $G = \langle V, E, w \rangle$ , a *path* (from  $v_1$  to  $v_k$ ) is a finite sequence  $\pi = v_1, v_2, \dots, v_k$  of vertices ( $v_i \in V$  for all  $i$ ) s.t.  $(v_i, v_{i+1}) \in E$  for all  $1 \leq i \leq k - 1$ . A *cycle* is a path  $v_1, v_2, \dots, v_k$  s.t.  $v_1 = v_k$ . The *weight*  $w(\pi)$  of a path  $\pi = v_1, v_2, \dots, v_k$  is the sum of its edge weights, i.e.  $\sum_{i=1}^{k-1} w(v_i, v_{i+1})$ . A path  $\pi$  (and, in particular, a cycle) is *negative* iff  $w(\pi) < 0$ . A path  $\pi = v_1, v_2, \dots, v_k$  is called a *shortest path* from  $v_1$  to  $v_k$  iff there is no other path  $\pi'$  from  $v_1$  to  $v_k$  s.t.  $w(\pi') < w(\pi)$  (observe that there could be several shortest paths from  $v_1$  to  $v_k$ , but all of them have necessarily the same weight). In a graph that contains no negative cycle, it is well-known that there exists always a shortest path between two pairs of nodes, provided that there exists a path between those nodes. In such graphs  $G$ , we note  $sp_G(x, y)$  the weight  $w(\pi)$  of any shortest path  $\pi$  from  $x$  to  $y$  (and we let  $sp_G(x, y) = +\infty$  if there is no path from  $x$  to  $y$  in  $G$ ). The problem asking to compute  $sp_G(x, y)$  for all pairs of nodes  $(x, y)$  (or to declare

the value  $sp_G(x, y)$  as undefined when the graph contains a negative cycle) is known in the literature as the *all-pairs shortest path problem* [12].

This problem allows us to solve the satisfiability and tightening problems. In [16], the author shows that:

► **Theorem 7** ([16]). *A constraint  $\varphi$  is satisfiable iff its graph  $G_\varphi$  contains no negative cycle.*

Moreover, the tightening of constraints has been considered in the setting of timed systems, and has been shown equivalent to the computation of all-pairs shortest paths:

► **Theorem 8** ([6]). *Given a satisfiable constraint  $\varphi$  (on set of variables  $\mathcal{V}$  and with corresponding graph  $G_\varphi$ ), the tightest constraint  $\varphi'$  s.t.  $\llbracket \varphi \rrbracket = \llbracket \varphi' \rrbracket$  is the constraint:*

$$\bigwedge_{x, y \in \mathcal{V}} x - y \leq sp_{G_\varphi}(x, y).$$

The reduction to shortest paths applies only when the constraint is satisfiable. Otherwise, the graph contains a negative cycle (by Theorem 7) and the notion of shortest path makes no sense.

Thus, in order to solve both satisfiability and tightening in practice, one can rely on one of the algorithms for the all-pairs shortest path problem from the literature (see [12] for a survey). All of these algorithms run in polynomial time. For example, one could use Johnson's algorithm [10], which runs in time  $O(|V|^2 \log(|V|) + |V||E|)$  and detects negative cycles before computing all-pairs shortest paths, if the graph contains no negative cycle.

► **Example 9.** Let us come back to the Chronoland example. The graph in Figure 3 contains no negative cycle, hence the overall constraint  $\varphi$  of Chronoland is satisfiable. We now come to tightening. The result of the all-pairs shortest path computation is given in appendix (Figure 4) for reference. The most relevant results of computing all-pairs shortest paths in the graph of Figure 3 are summarised in Figure 2. For instance, the upper bound of 1260 on  $\text{beg}(S_1)$  is obtained by considering the atomic constraint of the form  $\text{beg}(S_1) - z_0 \leq sp_G(\text{beg}(s_1), z_0)$  in the tightened constraint. The value  $sp_G(\text{beg}(s_1), z_0)$  is obtained by considering the path  $\text{beg}(S_1), \text{end}(S_1), \text{beg}(S_2), \text{end}(S_2), \text{end}(K_2), z_0$  of total weight  $-20 + -20 + 1300 = 1260$ . Other values are obtained similarly.

**Checking sure-contemporaneity.** Let us now explain how sure-contemporaneity (Problem 4) can be checked against the graph  $G_\varphi$  (corresponding to constraint  $\varphi$ ) *in constant time*, provided that  $\varphi$  is tight. We start by defining the Inclusion Checking problem, which will be useful to this end. This problem checks whether the set of chronologies  $\llbracket \varphi_1 \rrbracket$  represented by a constraint  $\varphi_1$  is included into the set of chronologies  $\llbracket \varphi_2 \rrbracket$  represented by another constraint  $\varphi_2$ :

► **Problem 10.** *The Inclusion problem asks, given two constraints  $\varphi_1$  and  $\varphi_2$ , whether  $\llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket$ .*

We have already seen in an example above that  $\varphi_1 \preceq \varphi_2$  implies  $\llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket$ , but that, in general, the reverse implication is not true. It becomes, however, true, when the constraints have been tightened. As a matter of fact, having  $\varphi_1$  tight is sufficient (see [3] for a reference):

► **Proposition 11.** *For all pairs of constraints  $\varphi_1$  and  $\varphi_2$ , the two following statements hold:*

$$\begin{aligned} & \varphi_1 \preceq \varphi_2 \text{ implies } \llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket, \\ & (\llbracket \varphi_1 \rrbracket \subseteq \llbracket \varphi_2 \rrbracket \text{ and } \varphi_1 \text{ is tight}) \text{ implies } \varphi_1 \preceq \varphi_2. \end{aligned}$$

We now come back to the sure-contemporaneity problem, and show that it can be reduced to the inclusion problem. The definition of the sure-contemporaneity problem means that, for

all chronologies  $\mathcal{C} \in \llbracket \varphi \rrbracket$ :  $p_1$  and  $p_2$  intersect in  $\mathcal{C}$ , i.e.,  $\ell(\mathcal{C}(p_1)) \leq u(\mathcal{C}(p_2))$  and  $\ell(\mathcal{C}(p_2)) \leq u(\mathcal{C}(p_1))$ . Clearly, this holds iff  $\llbracket \varphi \rrbracket \subseteq \llbracket \varphi_{p_1, p_2}^{\text{sync}} \rrbracket$ , where:

$$\varphi_{p_1, p_2}^{\text{sync}} = \text{beg}(p_1) \leq \text{end}(p_2) \wedge \text{beg}(p_2) \leq \text{end}(p_1). \quad (1)$$

However,  $\varphi_{p_1, p_2}^{\text{sync}}$  is equivalent to  $\text{beg}(p_1) - \text{end}(p_2) \leq 0 \wedge \text{beg}(p_2) - \text{end}(p_1) \leq 0$ . Thus, using Proposition 11, and assuming  $\varphi$  is tight, we deduce that  $\llbracket \varphi \rrbracket \subseteq \llbracket \varphi_{p_1, p_2}^{\text{sync}} \rrbracket$  iff  $\varphi$  constraints  $\text{beg}(p_1) - \text{end}(p_2)$  and  $\text{beg}(p_2) - \text{end}(p_1)$  to be non-positive. Thus, we obtain a constant time procedure to check the sure-contemporaneity of two periods  $p_1$  and  $p_2$  on the graph  $G_\varphi$  of a tight constraint  $\varphi$ :

► **Proposition 12.** *For all tight constraint  $\varphi$  on  $\mathcal{P}$  (with corresponding graph  $G_\varphi = (V, E, w)$ ), for all pairs of periods  $p_1$  and  $p_2$ , there is a sure-contemporaneity between  $p_1$  and  $p_2$  in  $\varphi$  iff  $w(\text{beg}(p_1), \text{end}(p_2)) \leq 0$  and  $w(\text{beg}(p_2), \text{end}(p_1)) \leq 0$  (assuming  $w(x, y) = +\infty$  when  $(x, y) \notin E$ ).*

► **Example 13.** To answer our question ‘has  $K_1$  built  $S_2$ ?’ from the introduction, we can check whether there is a sure-contemporaneity between  $K_1$  and  $S_2$ . By proposition 12, there is *no sure-contemporaneity* iff either  $sp_{\text{Chrono}}(\text{beg}(K_1), \text{end}(S_2)) > 0$  or  $sp_{\text{Chrono}}(\text{beg}(S_2), \text{end}(K_1)) > 0$  (see Figure 3 for Chrono). While the path  $\text{beg}(K_1), \text{beg}(S_1), \text{end}(S_1), \text{beg}(S_2), \text{end}(S_2)$  is indeed negative, one can check that there all paths from  $\text{beg}(S_2)$  to  $\text{end}(K_1)$  are positive (actually,  $sp_{\text{Chrono}}(\text{beg}(S_2), \text{end}(K_1)) = 80$ , see Appendix A). Hence, there is no sure-contemporaneity between  $K_1$  and  $S_2$ , so the available archaeological data does not allow to say for sure that  $K_1$  built  $S_2$ .

**Checking Possible-Contemporaneity.** As with the sure-contemporaneity problem, we first rephrase the definition of the possible-contemporaneity problem using the  $\varphi_{p_1, p_2}^{\text{sync}}$  constraint from equation (1). Since there must be only one chronology compatible with the constraint  $\varphi$  in which  $p_1$  and  $p_2$  intersect, and since the set of such chronologies is characterised by  $\varphi_{p_1, p_2}^{\text{sync}}$  from equation (1), we have:

► **Lemma 14.** *For all constraints  $\varphi$  on set of periods  $\mathcal{P}$ , and all pairs of periods  $p_1, p_2 \in \mathcal{P}$ : there is a possible-contemporaneity between  $p_1$  and  $p_2$  iff  $\varphi \wedge \varphi_{p_1, p_2}^{\text{sync}}$  is satisfiable.*

Based on this characterisation, we obtain a simple algorithm to check possible-contemporaneity on tight constraints (in the spirit of Proposition 12 for sure-contemporaneity):

► **Proposition 15.** *For all tight constraint  $\varphi$  on  $\mathcal{P}$  (with corresponding graph  $G_\varphi = (V, E, w)$ ), for all pairs of periods  $p_1$  and  $p_2$ , there is a possible-contemporaneity between  $p_1$  and  $p_2$  in  $\varphi$  iff  $w(\text{end}(p_2), \text{beg}(p_1)) \geq 0$  and  $w(\text{end}(p_1), \text{beg}(p_2)) \geq 0$  (assuming  $w(x, y) = +\infty$  when  $(x, y) \notin E$ ).*

► **Example 16.** We come back again to the Chronoland example and our question asking whether  $K_1$  has built  $S_2$ . We check whether there is a possible-contemporaneity between  $K_1$  and  $S_2$  (remember from Example 13 that there is no *sure*-contemporaneity between them). By Proposition 15, there is *no possible-contemporaneity* iff  $sp_{\text{Chrono}}(\text{end}(S_2), \text{beg}(K_1)) < 0$  or  $sp_{\text{Chrono}}(\text{end}(K_1), \text{beg}(S_2)) < 0$ . The latter holds since the path  $\text{end}(K_1), \text{beg}(K_1), \text{beg}(S_1), \text{end}(S_1), \text{beg}(S_2)$  has weight  $15 + -20 = -5$  (see Appendix A). Hence, there is *no possible-contemporaneity* between  $K_1$  and  $S_2$ . This result is stronger than the one from Example 13 and allows to rule out for sure that king  $K_1$  built stratum  $S_2$ .

The result of Proposition 15 is not straightforward and requires a proof. We start by giving some intuitions. First observe that we consider a constraint  $\varphi$ , which we assume to be satisfiable (otherwise there is trivially no possible-contemporaneity), and tight. Then, the proof is based on the following observation: taking the conjunction of  $\varphi$  and  $\varphi_{p_1, p_2}^{\text{sync}}$  (Lemma 14) amounts to computing the graph  $G' = (V, E', w')$  from  $G_\varphi = (V, E, w)$  as follows (assuming  $w(x, y) = +\infty$  if  $(x, y) \notin E$ ):

$$\blacksquare E' = E \cup \{(\text{beg}(p_2), \text{end}(p_1)), (\text{beg}(p_1), \text{end}(p_2))\};$$

- $w'(\text{beg}(p_2), \text{end}(p_1)) = \min\{w(\text{beg}(p_2), \text{end}(p_1)), 0\}$ ;
- $w'(\text{beg}(p_1), \text{end}(p_2)) = \min\{w(\text{beg}(p_1), \text{end}(p_2)), 0\}$ ;
- $w'(e) = w(e)$  for all  $e \in E \setminus \{(\text{beg}(p_2), \text{end}(p_1)), (\text{beg}(p_1), \text{end}(p_2))\}$ .

That is,  $G'$  is obtained from  $G_\varphi$  by setting the weights of  $(\text{beg}(p_2), \text{end}(p_1))$  and  $(\text{beg}(p_1), \text{end}(p_2))$  to 0 if they had non-negative weights in  $G_\varphi$ . One can check that the constraint corresponding to  $G'$  is equivalent to  $\varphi \wedge \varphi_{p_1, p_2}^{\text{sync}}$ , so there is a possible-contemporaneity between  $p_1$  and  $p_2$  iff there is no negative cycle in  $G'$ , by Lemma 14.

Now assume that  $\varphi \wedge \varphi_{p_1, p_2}^{\text{sync}}$  is *not satisfiable* and thus  $G'$  contains a negative cycle. Since  $\varphi$  is tight and satisfiable,  $G_\varphi$  contains no negative cycle, hence the negative cycle in  $G'$  comes necessarily from the modification we have performed on  $(\text{beg}(p_1), \text{end}(p_2))$  and  $(\text{beg}(p_2), \text{end}(p_1))$ . Thus, there is, in  $G'$ , at least one negative cycle that contains  $(\text{beg}(p_1), \text{end}(p_2))$  or  $(\text{beg}(p_2), \text{end}(p_1))$ . For the sake of the discussion, let us assume the negative cycle contains  $(\text{beg}(p_2), \text{end}(p_1))$  and not  $(\text{beg}(p_1), \text{end}(p_2))$ , hence, the only reason for this negative cycle to exist in  $G'$  is because we have set  $w(\text{beg}(p_2), \text{end}(p_1))$  to 0, and thus, there is a negative *path* from  $\text{end}(p_1)$  to  $\text{beg}(p_2)$  in  $G'$  and  $G_\varphi$ . Since  $\varphi$  is tight, this implies that  $(\text{end}(p_1), \text{beg}(p_2))$  exists and has negative weight in  $G_\varphi$ . Conversely, if  $w(\text{end}(p_1), \text{beg}(p_2)) < 0$ , then, there is necessarily a negative cycle containing  $(\text{beg}(p_2), \text{end}(p_1))$  in  $G'$ , since  $w'(\text{beg}(p_2), \text{end}(p_1)) \leq 0$ , by construction. This explains intuitively why checking that both  $w(\text{end}(p_2), \text{beg}(p_1))$  and  $w(\text{end}(p_1), \text{beg}(p_2))$  are non-negative is necessary and sufficient to check possible-contemporaneity. This can be performed in  $O(1)$  on *tight* (and satisfiable) constraints. Let us now provide a formal proof that follows the line of the intuitions given above:

**Proof of Proposition 15.** We prove both directions of the iff. First let us show that a possible-contemporaneity between  $p_1$  and  $p_2$  implies  $w(\text{end}(p_2), \text{beg}(p_1)) \geq 0$  and  $w(\text{end}(p_1), \text{beg}(p_2)) \geq 0$ . We prove the contraposition, i.e., if either  $w(\text{end}(p_2), \text{beg}(p_1)) < 0$  or  $w(\text{end}(p_1), \text{beg}(p_2)) < 0$ , then there is no possible-contemporaneity between  $p_1$  and  $p_2$ . Assume that  $w(\text{end}(p_2), \text{beg}(p_1)) < 0$  (the case  $w(\text{end}(p_1), \text{beg}(p_2)) < 0$  is symmetrical), and consider the graph  $G' = \langle V, E', w' \rangle$  obtained, as described above. By definition of  $G'$ , and since  $w(\text{end}(p_2), \text{beg}(p_1)) < 0$ :  $w'(\text{end}(p_2), \text{beg}(p_1)) = w(\text{end}(p_2), \text{beg}(p_1)) < 0$ . Let us show that the cycle  $\text{end}(p_2), \text{beg}(p_1), \text{end}(p_1), \text{beg}(p_2), \text{end}(p_2)$  is negative in  $G'$ . Indeed, we have:

$$\begin{array}{ll}
 w'(\text{beg}(p_1), \text{end}(p_1)) \leq 0 & \text{True in all constraints: the beginning occurs before the end} \\
 w'(\text{beg}(p_2), \text{end}(p_2)) \leq 0 & \text{Same argument} \\
 w'(\text{end}(p_1), \text{beg}(p_2)) \leq 0 & \text{By construction of } G' \\
 w'(\text{end}(p_2), \text{beg}(p_1)) < 0 & \text{By the above arguments.}
 \end{array}$$

Hence, the weight of the  $\text{end}(p_2), \text{beg}(p_1), \text{end}(p_1), \text{beg}(p_2), \text{end}(p_2)$  cycle is indeed negative. However, by construction  $G'$  is the graph that corresponds to  $\varphi \wedge \varphi_{p_1, p_2}^{\text{sync}}$ , hence this constraint is not satisfiable. By Lemma 14, there is no possible-contemporaneity between  $p_1$  and  $p_2$  in  $\varphi$ .

For the other direction, let us show that:

$$w(\text{end}(p_2), \text{beg}(p_1)) \geq 0 \text{ and } w(\text{end}(p_1), \text{beg}(p_2)) \geq 0 \quad (2)$$

implies that there is a possible-contemporaneity between  $p_1$  and  $p_2$  in  $\varphi$ . Following Lemma 14, we show that (2) implies that  $\varphi \wedge \varphi_{p_1, p_2}^{\text{sync}}$  is satisfiable. To show this, we rely again on the graph  $G'$  described above: we proceed by contradiction and assume that (2) holds but that  $G'$  contains a negative cycle. We consider several cases:

1. The negative cycle contains neither the  $(\text{beg}(p_2), \text{end}(p_1))$ , nor the  $(\text{beg}(p_1), \text{end}(p_2))$  edge. Since these two edges are the only ones that have been modified when building  $G'$  from  $G_\varphi$ , we conclude that the negative cycle is already present in  $G_\varphi$ . This is a contradiction since we have assumed that  $\varphi$  is satisfiable.

2. The negative cycle contains only one of the two edges  $(\text{beg}(p_2), \text{end}(p_1))$  and  $(\text{beg}(p_1), \text{end}(p_2))$ . Wlog, we assume that the negative cycle of  $G'$  contains  $(\text{beg}(p_2), \text{end}(p_1))$ , i.e. it is of the form:

$$\text{beg}(p_2) \xrightarrow{w'(\text{beg}(p_2), \text{end}(p_1))} \underbrace{\text{end}(p_1) \xrightarrow{w_1} v_1 \xrightarrow{w_2} \dots \xrightarrow{w_n} v_n \xrightarrow{w_{n+1}} \text{beg}(p_2)}_{\pi}$$

where  $w_1 = w'(\text{end}(p_1), v_1)$ ,  $w_i = w'(v_{i-1}, v_i)$  for all  $2 \leq i \leq n$ ,  $w_{n+1} = w'(v_n, \text{beg}(p_2))$ , and neither  $(\text{beg}(p_2), \text{end}(p_1))$ , nor  $(\text{beg}(p_1), \text{end}(p_2))$  occur in  $\pi$ . Since this cycle is negative in  $G'$ :

$$w'(\text{beg}(p_2), \text{end}(p_1)) + \sum_{i=1}^{n+1} w_i < 0.$$

Recall that, by construction of  $G'$ :  $w'(\text{beg}(p_2), \text{end}(p_1)) \leq 0$ . We consider two further sub-cases:

- a. If  $w'(\text{beg}(p_2), \text{end}(p_1)) = 0$ , then  $\sum_{i=1}^{n+1} w_i < 0$ , i.e., the total weight of  $\pi$  is non-positive. However, since all edges occurring in  $\pi$  occur with the same weight in  $G_\varphi$ , and since  $\pi$  starts in  $\text{end}(p_1)$  and ends in  $\text{beg}(p_2)$ , we conclude that the shortest path between  $\text{end}(p_1)$  and  $\text{beg}(p_2)$  is  $< 0$  in  $G_\varphi$ . Since  $\varphi$  is assumed to be tight, this implies that  $w(\text{end}(p_1), \text{beg}(p_2)) < 0$ , which is a contradiction with our hypothesis (2).
- b. If  $w'(\text{beg}(p_2), \text{end}(p_1)) < 0$ , then by construction of  $G'$ , this edge had the same weight in  $G_\varphi$ , i.e.,  $w'(\text{beg}(p_2), \text{end}(p_1)) = w(\text{beg}(p_2), \text{end}(p_1)) < 0$ . Since all the edges in  $\pi$  were also present in  $G_\varphi$  with the same weight, we conclude that the negative cycle we have identified in  $G'$  is also present in  $G_\varphi$ . This is a contradiction since we have assumed that  $\varphi$  is satisfiable.
3. The negative cycle contains both  $(\text{beg}(p_2), \text{end}(p_1))$  and  $(\text{beg}(p_1), \text{end}(p_2))$ , i.e. it is of the form:

$$\begin{aligned} \text{beg}(p_1) \xrightarrow{w'(\text{beg}(p_1), \text{end}(p_2))} \underbrace{\text{end}(p_2) \xrightarrow{w_1} v_1 \xrightarrow{w_2} \dots \xrightarrow{w_n} v_n \xrightarrow{w_{n+1}} \text{beg}(p_2)}_{\pi_1} \\ \xrightarrow{w'(\text{beg}(p_2), \text{end}(p_1))} \underbrace{\text{end}(p_1) \xrightarrow{w'_1} v'_1 \xrightarrow{w'_2} \dots \xrightarrow{w'_\ell} v'_\ell \xrightarrow{w'_{\ell+1}} \text{beg}(p_1)}_{\pi_2} \end{aligned}$$

where  $w_1 = w'(\text{end}(p_2), v_1)$ ; for all  $2 \leq i \leq n$ :  $w_i = w'(v_{i-1}, v_i)$ ;  $w_{n+1} = w'(v_n, \text{beg}(p_2))$ ;  $w'_1 = w'(\text{end}(p_1), v'_1)$ ; for all  $1 \leq i \leq \ell$ :  $w'_i = w'(v'_{i-1}, v'_i)$ ;  $w'_{\ell+1} = w'(v'_\ell, \text{beg}(p_1))$ ; and  $(\text{beg}(p_2), \text{end}(p_1))$ ,  $(\text{beg}(p_1), \text{end}(p_2))$  occur neither in  $\pi_1$  nor in  $\pi_2$ . Since this cycle is negative in  $G'$ , we have:

$$w'(\text{beg}(p_1), \text{end}(p_2)) + \sum_{i=1}^{n+1} w_i + w'(\text{beg}(p_2), \text{end}(p_1)) + \sum_{i=1}^{\ell+1} w'_i < 0 \quad (3)$$

Since, by construction of  $G'$ :  $w'(\text{beg}(p_2), \text{end}(p_1)) \leq 0$  and  $w'(\text{beg}(p_1), \text{end}(p_2)) \leq 0$ , we consider four further sub-cases:

- a. First,  $w'(\text{beg}(p_2), \text{end}(p_1)) = w'(\text{beg}(p_1), \text{end}(p_2)) = 0$ . Then, (3) yields:

$$\sum_{i=1}^{n+1} w_i + \sum_{i=1}^{\ell+1} w'_i < 0.$$

Hence, one of these two sums must be  $< 0$ . Wlog, let us assume  $\sum_{i=1}^{n+1} w_i < 0$ , i.e., the weight of  $\pi_1$  is non-positive (the arguments carry on when the overall weight of  $\pi_2$  is non-positive instead). Since all the edges of  $\pi_1$  were already present in  $G$  with the same weights, we conclude that the shortest path from  $\text{end}(p_2)$  to  $\text{beg}(p_2)$  is  $< 0$  in  $G$ . Since we have assumed that  $\varphi$  is tight, this implies that  $w(\text{end}(p_2), \text{beg}(p_2)) < 0$ , hence,  $\varphi$  contains an atomic constraint of the form  $\text{end}(p_2) - \text{beg}(p_2) \leq c$  from some  $c < 0$ . However, this renders  $\varphi$  unsatisfiable, because all constraints imply that  $\text{beg}(p) - \text{end}(p) \leq 0$  for all periods  $p$ . Contradiction.

b. Second  $w'(\text{beg}(p_2), \text{end}(p_1)) < 0$  and  $w'(\text{beg}(p_1), \text{end}(p_2)) = 0$ . Then, (3) yields:

$$\sum_{i=1}^{n+1} w_i + w'(\text{beg}(p_2), \text{end}(p_1)) + \sum_{i=1}^{\ell+1} w'_i < 0. \quad (4)$$

However, by construction of  $G'$ ,  $w'(\text{beg}(p_2), \text{end}(p_1)) < 0$  implies that the  $(\text{beg}(p_2), \text{end}(p_1))$  was already present in  $G$  with the same weight, i.e.  $w(\text{beg}(p_2), \text{end}(p_1)) < 0$ . Moreover, all edges in  $\pi_1$  and  $\pi_2$  are also present in  $G$  with the same weight as in  $G'$ . Thus, we conclude from (4) that the  $\text{end}(p_2), v_1, \dots, v_n, \text{beg}(p_2), \text{end}(p_1), v'_1, \dots, v'_\ell, \text{beg}(p_1)$  path exists in  $G$  with non-positive weight. Hence, the shortest path from  $\text{end}(p_2)$  to  $\text{beg}(p_1)$  in  $G$  has weight  $< 0$ . Since we have assumed that  $\varphi$  is tight, we conclude that  $w(\text{end}(p_2), \text{beg}(p_1)) < 0$ , which contradict our hypothesis (2). Contradiction.

c. Third,  $w'(\text{beg}(p_2), \text{end}(p_1)) = 0$  and  $w'(\text{beg}(p_1), \text{end}(p_2)) < 0$  is treated as the previous case.

d. Finally, when  $w'(\text{beg}(p_2), \text{end}(p_1)) < 0$  and  $w'(\text{beg}(p_1), \text{end}(p_2)) < 0$ , we conclude that all the edges in the negative cycle we have identified are already present in  $G$  with the same weight, i.e., the  $\text{beg}(p_1), \text{end}(p_2), v_1, \dots, v_n, \text{beg}(p_2), \text{end}(p_1), v'_1, \dots, v'_\ell, \text{beg}(p_1)$  cycle has negative weight in  $G$ , hence  $\varphi$  is not satisfiable. Contradiction.

## 4 Conclusion and future works

This paper presents a theoretical framework for the modelling of chronological constraints relevant to archaeological research. Within this framework, algorithms have been presented to solve four basic chronological problems (satisfiability, tightening, sure- and possible- contemporaneity) that are usually addressed in a non-formal way by the archaeological community. As shown here for a toy example featuring only two kings and two archaeological strata (Figure 1), solving these problems manually is tedious and error-prone, especially when it comes to obtaining optimal bounds on dates and duration (tightening). On real-life archaeological cases, featuring dozens of periods and synchronisms, obtaining reliable and optimal results is virtually impossible without the help of a formal computational approach as the one advocated for here.

We further contend that the application of our algorithms to real-life archaeological test-cases might provide significant advances to current chronological debates, through the detection of (yet unnoticed) unsatisfiable sets of chronological constraints, and through the computation of improved chronological estimates through our tightening procedure. An automated technique also allows archaeologist to test quickly the implications of new hypothesis on chronological models.

The next steps of this research are therefore both practical and theoretical. On the *practical* side, we wish to develop a comprehensive methodology for chronological research in archaeology, including a user-friendly tool that will allow archaeologists to specify, through a dedicated high-level constraint language, and manipulate their own chronological models. We also want to apply this methodology on concrete case studies from the archaeological literature. On the *theoretical* side, it is clear that the development of concrete case studies will raise new theoretical questions. One such questions we can already mention is ‘how to provide the archaeological user with a meaningful *witness* of non-satisfiability?’ when a constraint is found to be unsatisfiable. In such as case, the user would wish to understand why the system is unsatisfiable, and also be provided with hints as to how the system could be rendered satisfiable through the removal (or relaxing) of a limited number of constraints.
